## On Optimization of Shape and Topology

Cameron Talischi, Glaucio H. Paulino
Department of Civil and Environmental Engineering University of Illinois at Urbana-Champaign

## Introduction:

$\square$ The goal of optimal shape design is to find the most efficient shape of a physical system
$\square$ The response is captured by the solution $\mathbf{u}_{\omega}$ to a boundary value problem that in turn depends on the given shape $\omega$

$$
\inf _{\omega \subseteq \Omega} J\left(\omega, \mathbf{u}_{\omega}\right) \quad \text { where } \quad \mathcal{B}\left(\mathbf{u}_{\omega}, \mathbf{v} ; \omega\right)=\ell(\mathbf{v}), \forall \mathbf{v} \in \mathcal{V}
$$

$\mathcal{B}(\mathbf{u}, \mathbf{v} ; \omega)=\int_{\Omega} \nabla \mathbf{u}:\left[\chi_{\omega} \mathbf{C}^{+}+\left(1-\chi_{\omega}\right) \mathbf{C}^{-}\right]: \nabla \mathbf{v} \mathrm{d} \mathbf{x}, \quad \ell(\mathbf{v})=\int_{\Gamma_{N}} \mathbf{t} \cdot \mathbf{v} \mathrm{~d} s$

## Restriction setting:

- If $\chi_{n}, \hat{\chi} \in L^{\infty}(\Omega ;[0,1])$ such that $\chi_{n} \rightarrow \hat{\chi}$ in $L^{1}(\Omega)$, then, up to a subsequence, the associated state solutions also converge, i.e., $\mathbf{u}_{\chi_{n}} \rightarrow \mathbf{u}_{\hat{\chi}}$ in $H^{1}\left(\Omega ; \mathbb{R}^{d}\right)$
- It follows that compactness in $L^{1}(\Omega)$ topology is a sufficient condition for existence of solutions
- A well-known example is the space of shapes with bounded perimeter:

$$
\mathcal{A}=\left\{\chi \in B V(\Omega ;\{0,1\}): \int_{\Omega}|\nabla \chi| \mathrm{d} \mathbf{x} \leq \bar{P}\right\}
$$

## Continuous parametrization:

## Optimization problem:

Composite objective:

$$
\begin{aligned}
& \min _{\rho \in \mathcal{A}} F(\rho):=J(\rho)+R(\rho) \\
& J(\rho)=\int_{\Gamma_{N}} \mathbf{t} \cdot \mathbf{u}_{\rho} \mathrm{d} s+\lambda \int_{\Omega} \rho \mathrm{d} \mathbf{x} \\
& R(\rho)=\frac{\beta}{2} \int_{\Omega}|\nabla \rho|^{2} \mathrm{~d} \mathbf{x} \equiv \frac{1}{2}\langle\rho, \mathcal{R} \rho\rangle, \quad \mathcal{R}=-\beta \Delta \\
& \mathcal{A}=\left\{\rho \in H^{1}(\Omega): 0 \leq \rho \leq 1\right\} \\
& \int_{\Omega} \nabla \mathbf{u}_{\rho}: \mathbf{C}_{\rho}: \nabla \mathbf{v} \mathrm{d} \mathbf{x}=\int_{\Gamma_{N}} \mathbf{t} \cdot \mathbf{v} \mathrm{~d} s, \forall \mathbf{v} \in \mathcal{V} \\
& \mathbf{C}_{\rho}=\rho^{\rho} \mathbf{C}^{+}+\left(1-\rho^{p}\right) \mathbf{C}^{-}
\end{aligned}
$$

Performance functional:

Regularizer:
Admissible densities:
State equation:

## Forward-backward splitting algorithm:

$\square$ We consider an optimization algorithm of the form:

$$
\rho_{n+1}=\underset{\rho \in \mathcal{A}}{\operatorname{argmin}} \frac{1}{2 \tau_{n}}\left\|\rho-\left[\rho_{n}-\tau_{n} J^{\prime}\left(\rho_{n}\right)\right]\right\|^{2}+R(\rho)
$$

The intuition is that the next iterate $\rho_{n+1}$ is close to the gradient descent update on $J$, i.e., $\rho_{n}-\tau_{n} J^{\prime}\left(\rho_{n}\right)$, while minimizing the regularizer $R(\rho)$
$\square$ Given constants $\tau_{0}>0$ and $0<\sigma<1$, the step size parameter is set to be

$$
\tau_{n}=\sigma^{k_{n}} \tau_{0}
$$

where $k_{n}$ is the smallest non-negative integer such that $\tau_{n}$ satisfies

$$
F\left(\rho_{n}\right)-F\left(\rho_{n+1}\right) \geq \frac{1}{2 \tau_{n}}\left\|\rho_{n}-\rho_{n+1}\right\|^{2}
$$

## Improving convergence:

$\square$ We consider the following generalization:

$$
\rho_{n+1}=\underset{\rho \in \mathcal{A}}{\operatorname{argmin}} J\left(\rho_{n}\right)+\left\langle J^{\prime}\left(\rho_{n}\right), \rho-\rho_{n}\right\rangle+\frac{1}{2 \tau_{n}}\left\langle\rho-\rho_{n}, \mathcal{H}_{n}\left(\rho-\rho_{n}\right)\right\rangle+R(\rho)
$$

where $\mathcal{H}_{n}$ is a bounded linear positive-definite operator
$\square$ The reciprocal approximation of compliance is its Taylor expansion in the intermediate field $\rho^{-1}$

$$
J_{\mathrm{rec}}\left(\rho ; \rho_{n}\right)=J\left(\rho_{n}\right)+\left\langle J^{\prime}\left(\rho_{n}\right), \rho-\rho_{n}\right\rangle+\frac{1}{2}\left\langle\rho-\rho_{n}, \frac{2 E\left(\rho_{n}\right)}{\rho}\left(\rho-\rho_{n}\right)\right\rangle
$$

where $E(\rho) \equiv p \rho^{p-1}\left[\nabla \mathbf{u}_{\rho}:\left(\mathbf{C}^{+}-\mathbf{C}^{-}\right): \nabla \mathbf{u}_{\rho}\right]$ is the gradient of compliance.
$\square$ We embed the same type of approximation into our quadratic model by setting

$$
\mathcal{H}_{n}=J_{\mathrm{rec}}^{\prime \prime}\left(\rho_{n} ; \rho_{n}\right)=\frac{2 E\left(\rho_{n}\right)}{\rho_{n}} \mathcal{I}
$$

## Performance of the algorithm:

| Algorithm | $\mathcal{H}_{n}$ | $\tau_{0}$ | \# Iter. | \# BT | $F$ | OC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| GP | - | 0.25 | $1000^{*}$ | 0 | 210.74 | $1.36 \mathrm{e}-4$ |
| GP | - | 0.5 | 568 | 79 | 210.68 | $8.94 \mathrm{e}-5$ |
| FBS | Identity | 1 | 316 | 0 | 210.97 | $9.94 \mathrm{e}-5$ |
| FBS | Identity | 2 | 215 | 154 | 210.91 | $9.81 \mathrm{e}-5$ |
| FBS | Reciprocal | 1 | 186 | 0 | 211.03 | $9.36 \mathrm{e}-5$ |
| FBS | Reciprocal | 2 | 91 | 39 | 211.00 | $9.75 \mathrm{e}-5$ |
| TM-FBS | Identity | 1 | 330 | 0 | 210.95 | $9.97 \mathrm{e}-5$ |
| TM-FBS | Identity | 2 | 151 | 78 | 210.94 | $5.90 \mathrm{e}-5$ |
| TM-FBS | Reciprocal | 1 | 179 | 0 | 211.03 | $9.45 \mathrm{e}-5$ |
| TM-FBS | Reciprocal | 2 | 85 | 34 | 211.00 | $8.07 \mathrm{e}-5$ |
| MMA | - | - | $1000^{*}$ | - | 213.39 | $1.91 \mathrm{e}-4$ |
